

# Removing nitrate from tile drain water using denitrification bioreactors

## Collaboration:

- Richard Smith and Mike Cahn - UCCE
- Ken Johnson and Luke Coletti - MBARI
- Cooperating growers

**Tile drains have high  $\text{NO}_3\text{-N}$  concentration, and can make up a substantial portion of surface flow during the irrigation season**

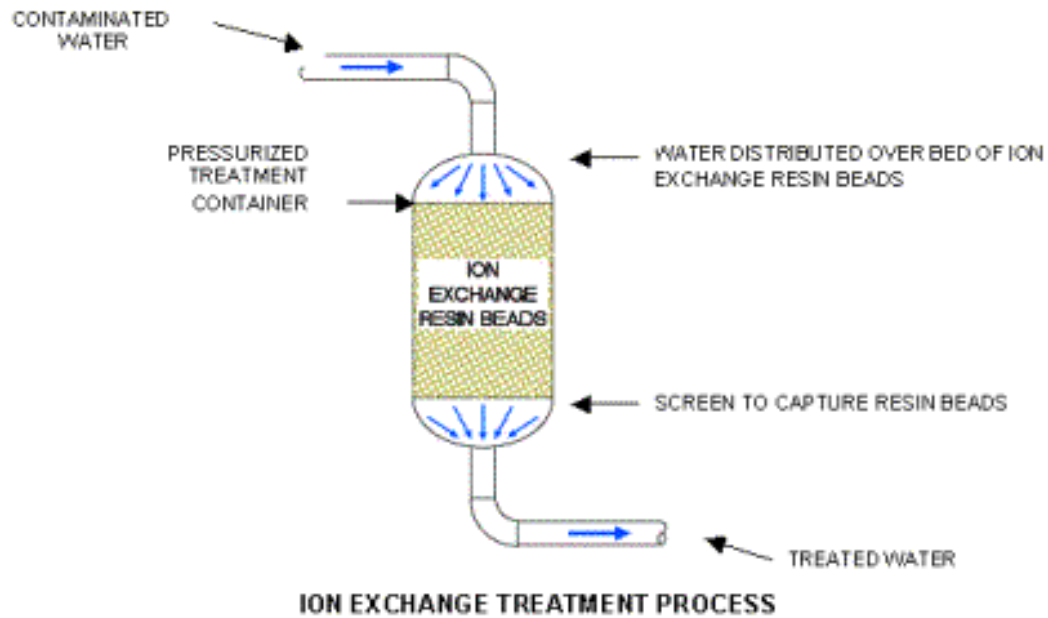

**How can  $\text{NO}_3\text{-N}$  be removed from tile drain water?**

- Ion exchange
- Biological denitrification

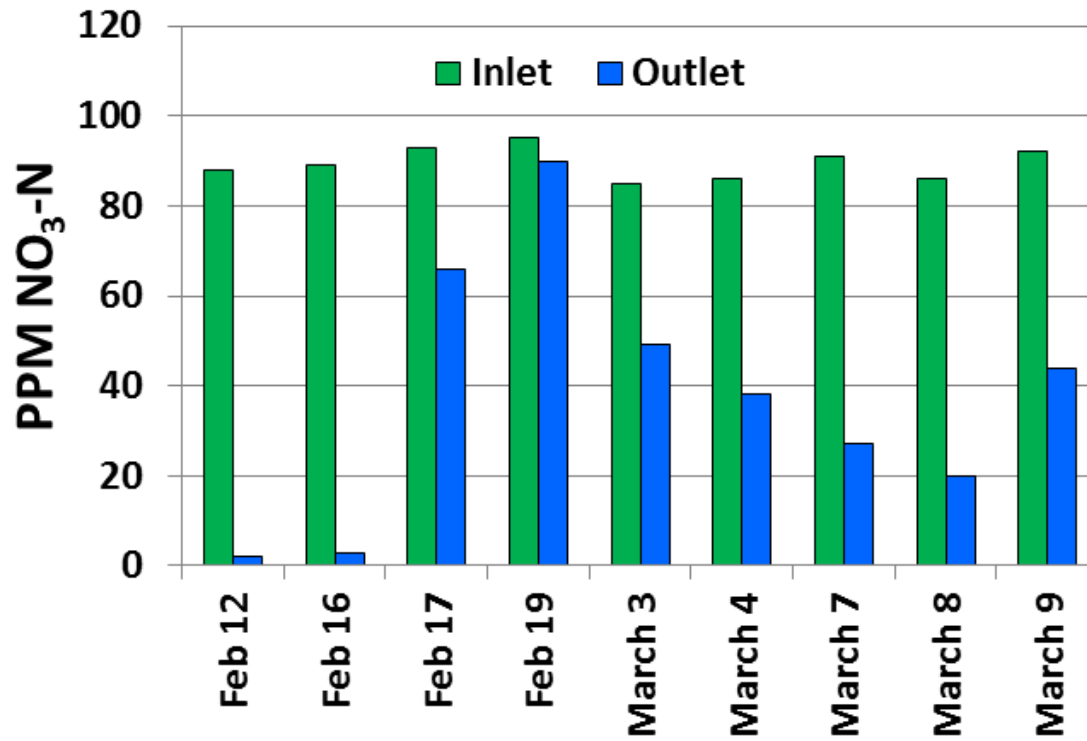

# Ion exchange for nitrate removal

- Captured  $\text{NO}_3\text{-N}$  can be reapplied as fertilizer
- High initial cost, complex operation and maintenance

# Recent performance:

# Salinas Valley wood chip denitrification bioreactors (DBRs) built in 2011:

**chipped construction waste from Monterey Regional Waste Management District**

# Bioreactor operation :

**Continuous pumping into DBRs  
from the tile drain sump, at a rate to  
allow about 2 days of residence time**

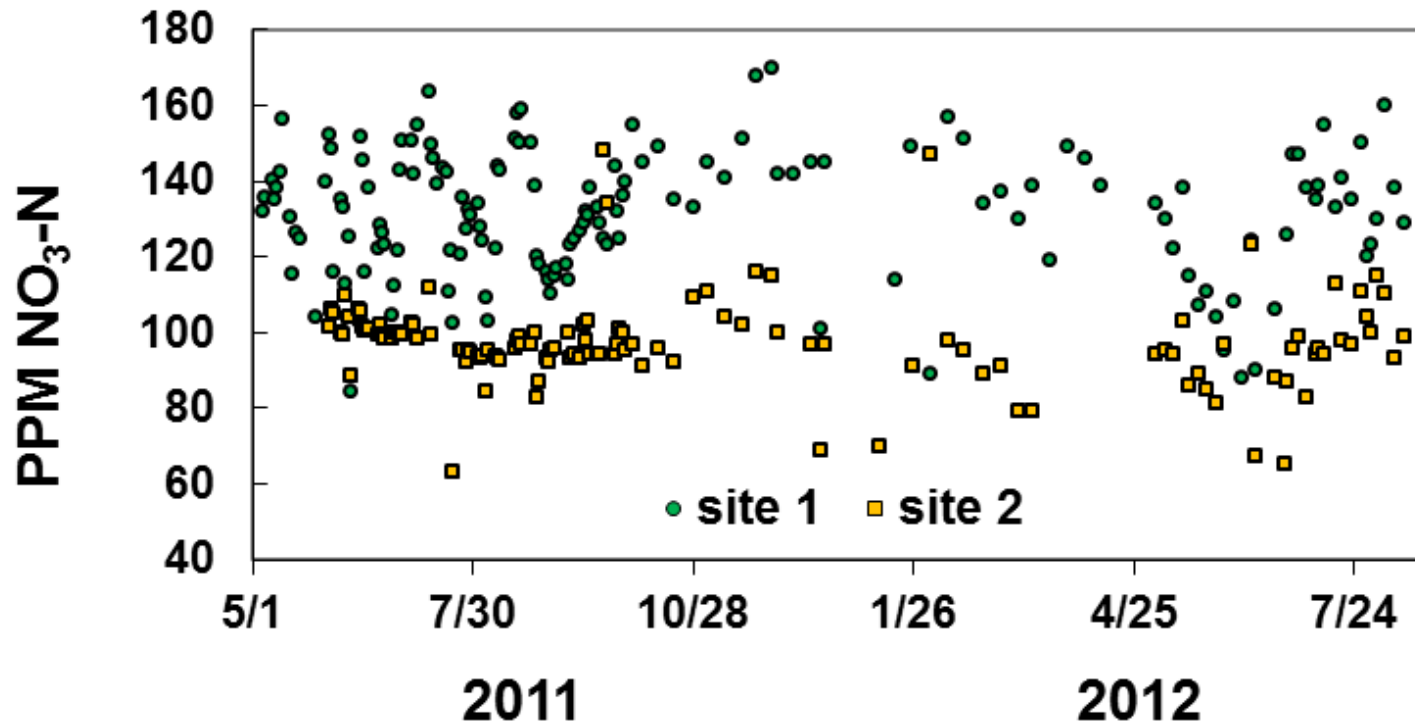

**DBR outlet drains into surface ditch**

# Tile drain $\text{NO}_3\text{-N}$ concentration is variable, but consistently high

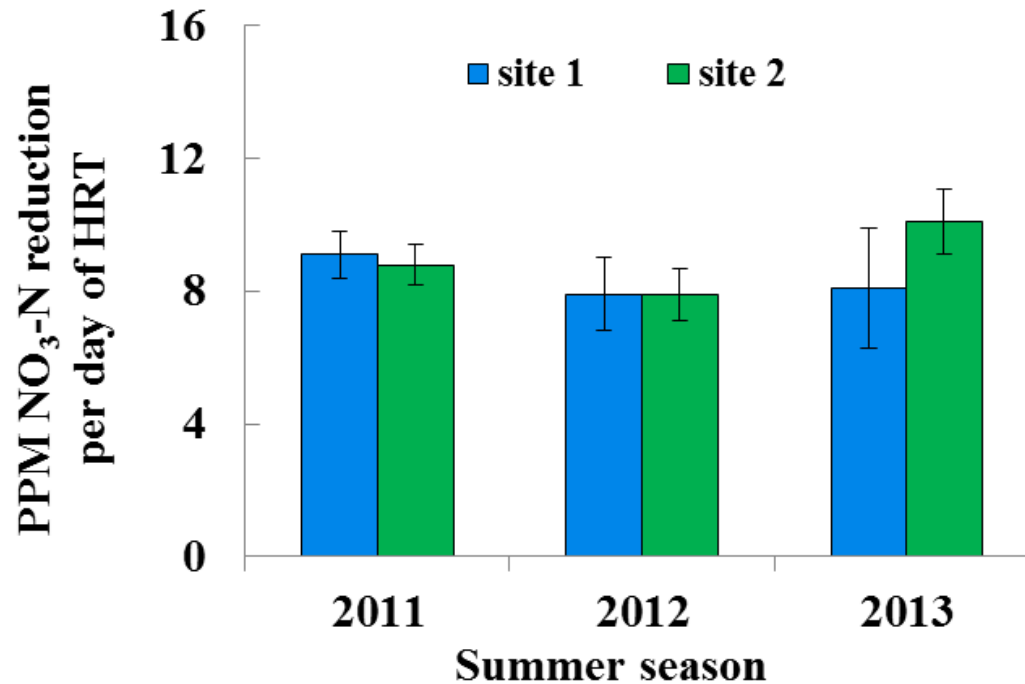

Pattern of  $\text{NO}_3\text{-N}$  in two tile drain systems in the Castroville area:

- While improved on-farm irrigation and N management can reduce this high N load, consistently achieving  $< 50$  PPM  $\text{NO}_3\text{-N}$  during the irrigation season is unlikely

Mean denitrification rates achieved during the irrigation season was consistent across the initial years of operation:

- PPM NO<sub>3</sub>-N reduction *per day of residence time*:

When operated in a 'passive' mode, this technology has significant limitations:

- The DBR 'footprint' would need to be very large to come close to meeting environmental NO<sub>3</sub>-N targets
- there is no effective way to handle fluctuations in N load

Why the difference in performance compared to 'managed' systems, in which denitrification rates can reach 10 PPM  $\text{NO}_3\text{-N}$  *per hour* ?

- 'Managed' systems inject soluble carbon to speed the denitrification process
  - methanol is commonly used

**2014:**

**Tested C injection in lab bioreactors:**

- **Aged wood chips taken from field bioreactors**
- **Evaluated the effect of methanol enrichment on denitrification rate**

**Results:**

- **Regardless of  $\text{NO}_3\text{-N}$  concentration, methanol carbon injected at a ratio of 1.4 (w/w basis) completely denitrified  $\text{NO}_3\text{-N}$  in less than 2 days of residence time**

**2015:**

## Optimizing field bioreactor management:

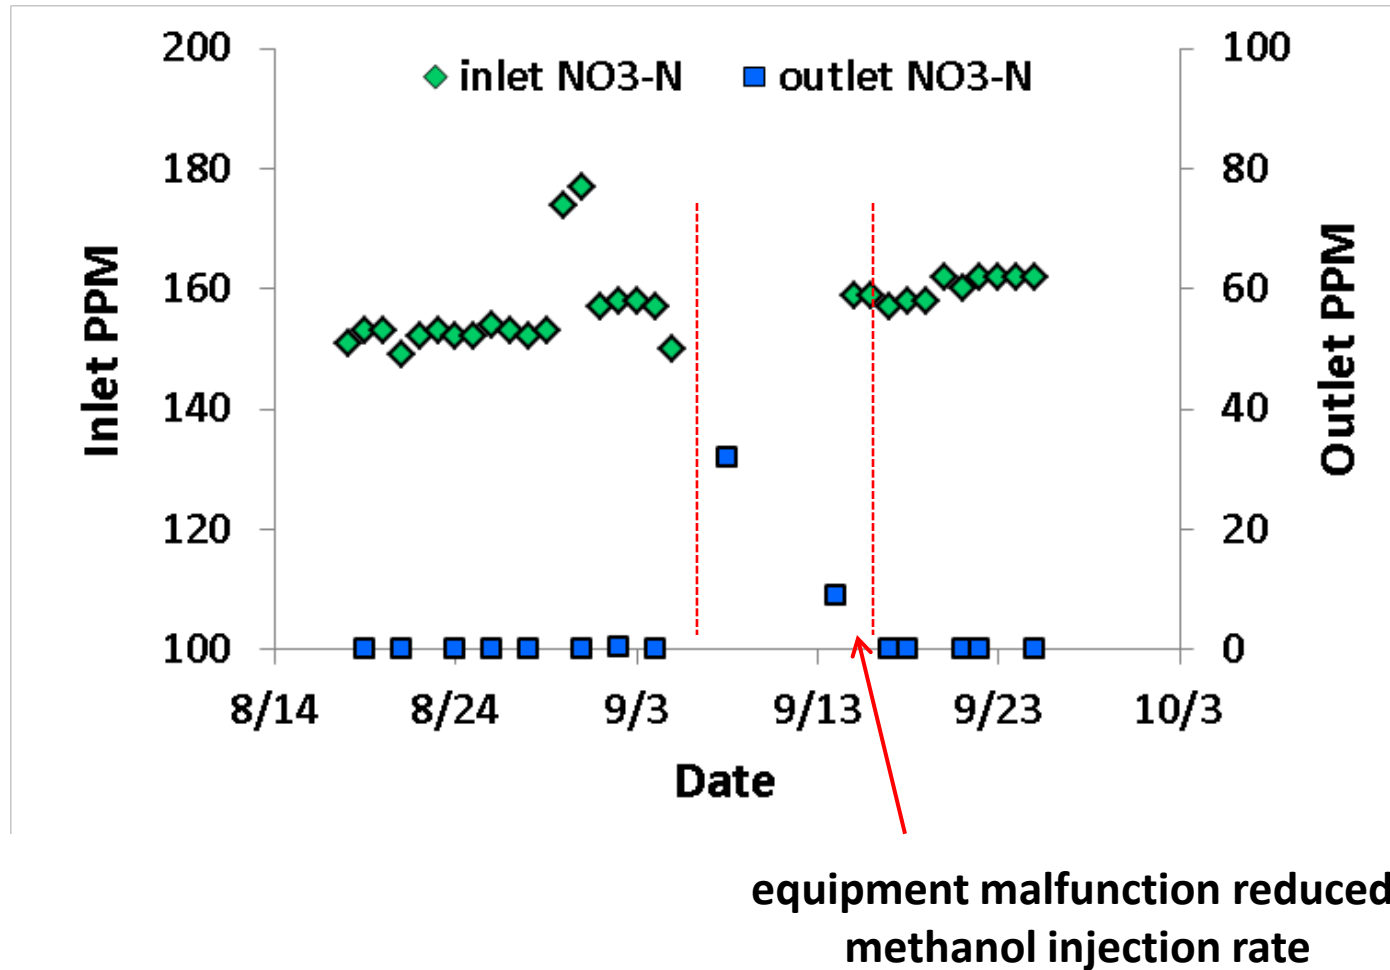

- Continuously adjust carbon enrichment to the real-time  $\text{NO}_3\text{-N}$  load

**ISUS (in-situ ultraviolet spectrophotometer)**

## Results:

- Injection ratio of  $\approx 1.4$  PPM C to 1 PPM  $\text{NO}_3\text{-N}$  gave complete nitrate removal in as little as 1.5 days of residence time

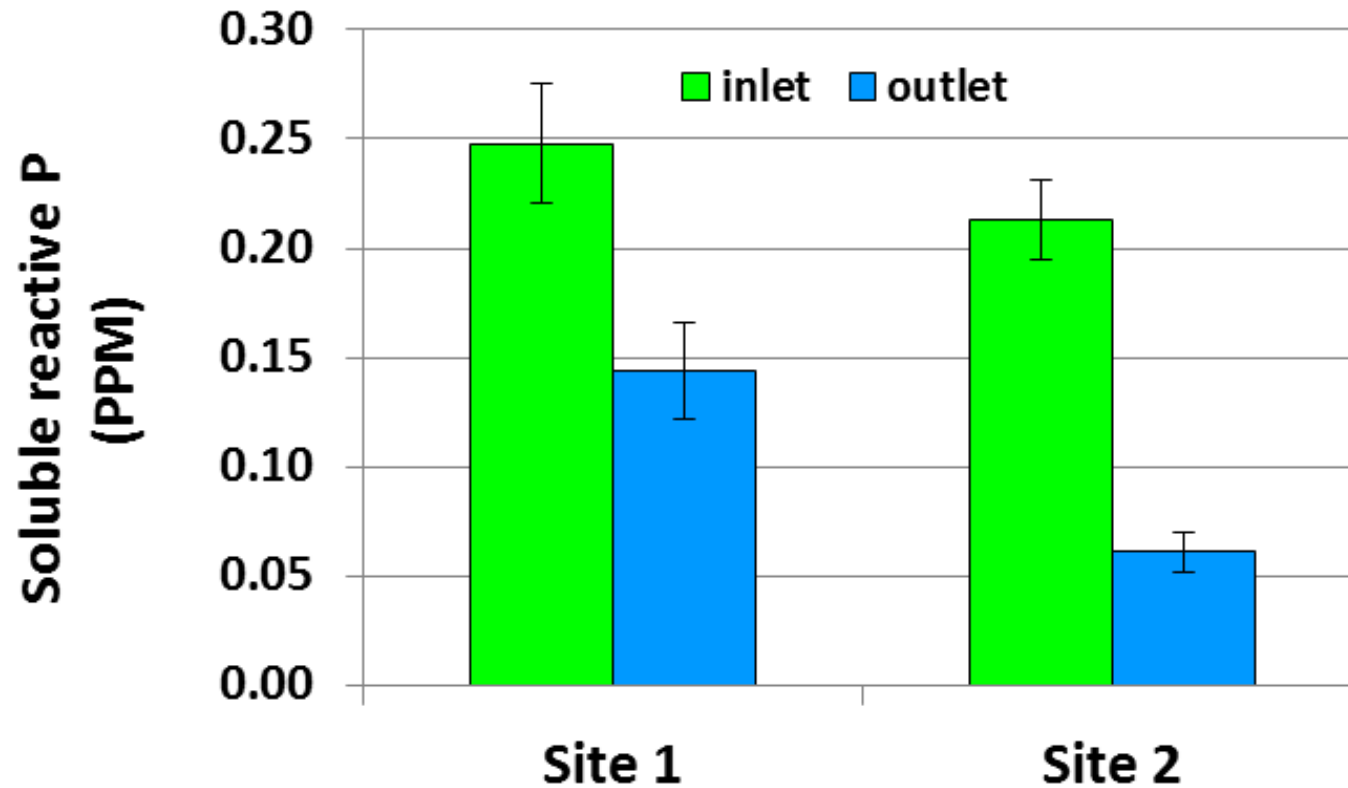

# What about N<sub>2</sub>O emission?

## Dissolved N<sub>2</sub>O release

	Dissolved N <sub>2</sub> O release (% of N removed)
Unenriched, or insufficiently enriched	> 4%
Methanol enriched @ 1.4 C:N ratio	< 0.2%

## Do bioreactors affect phosphorus concentration?

## Bioreactor costs

### Example:

- ranch of 100 farmed acres
- 35,000 gallons of tile drainage daily over 8 month irrigation season
- To retain 2 days of typical tile drain flow, a bioreactor would need to be about 100' long x 20' wide x 6' deep
- methanol @ \$1.00-1.30/lb C

### Cost:

- ≈ \$1.50-1.80/lb  $\text{NO}_3\text{-N}$  denitrified, not including the  $\text{NO}_3\text{-N}$  sensor/C injection system (about \$20K)

## **Conclusions:**

- **Passively operated bioreactors are severely limited:**
  - overwhelmed by high inlet  $\text{NO}_3\text{-N}$  concentration
  - inflexible in the face of highly fluctuating N loads
- **Controlling sediment is difficult in surface water treatment**
- **Carbon enrichment improves performance, but brings other issues**
  - added up-front cost
  - chemical storage / permitting
  - requires active management

A landscape photograph showing a body of water in the foreground, likely a wetland or marsh. The water is blue and reflects the sky. In the middle ground, there are several large clumps of tall, brown reeds or grasses. The background features rolling green hills and mountains under a clear blue sky. A small white boat is visible in the distance on the water.

**Could remediation technologies be combined?  
Could they be deployed on a regional scale?**

# More intensive denitrification approaches?

- Modular treatment systems
